

Space X Falcon 9 First Stage Landing Prediction

Lab 2: Data wrangling

Estimated time needed: 60 minutes

In this lab, we will perform some Exploratory Data Analysis (EDA) to find some patterns in the data and determine what would be the label for training supervised models.

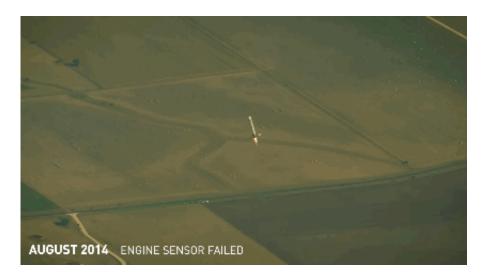

In the data set, there are several different cases where the booster did not land successfully. Sometimes a landing was attempted but failed due to an accident; for example, True Ocean means the mission outcome was successfully landed to a specific region of the ocean while False Ocean means the mission outcome was unsuccessfully landed to a specific region of the ocean. True RTLS means the mission outcome was successfully landed to a ground pad False RTLS means the mission outcome was unsuccessfully landed to a ground pad. True ASDS means the mission outcome was successfully landed on a drone ship False ASDS means the mission outcome was unsuccessfully landed on a drone ship.

In this lab we will mainly convert those outcomes into Training Labels with 1 means the booster successfully landed 0 means it was unsuccessful.

Falcon 9 first stage will land successfully

Several examples of an unsuccessful landing are shown here:

Objectives

Perform exploratory Data Analysis and determine Training Labels

- Exploratory Data Analysis
- Determine Training Labels

Install the below libraries

TASK 1: Calculate the number of launches on each site

The data contains several Space X launch facilities: Cape Canaveral Space Launch Complex 40 VAFB SLC 4E, Vandenberg Air Force Base Space Launch Complex 4E (SLC-4E), Kennedy Space Center Launch Complex 39A KSC LC **39A** .The location of each Launch Is placed in the column LaunchSite

Next, let's see the number of launches for each site.

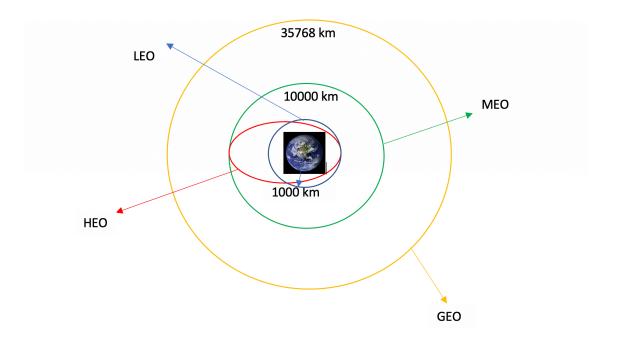

Use the method value_counts() on the column LaunchSite to determine the number of launches on each site:

Each launch aims to an dedicated orbit, and here are some common orbit types:

- **LEO**: Low Earth orbit (LEO) is an Earth-centred orbit with an altitude of 2,000 km (1,200 mi) or less (approximately one-third of the radius of Earth),[1] or with at least 11.25 periods per day (an orbital period of 128 minutes or less) and an eccentricity less than 0.25.[2] Most of the manmade objects in outer space are in LEO [1].
- **VLEO**: Very Low Earth Orbits (VLEO) can be defined as the orbits with a mean altitude below 450 km. Operating in these orbits can provide a number of benefits to Earth observation spacecraft as the spacecraft operates closer to the observation[2].
- GTO A geosynchronous orbit is a high Earth orbit that allows satellites to
 match Earth's rotation. Located at 22,236 miles (35,786 kilometers)
 above Earth's equator, this position is a valuable spot for monitoring
 weather, communications and surveillance. Because the satellite orbits at
 the same speed that the Earth is turning, the satellite seems to stay in
 place over a single longitude, though it may drift north to south," NASA
 wrote on its Earth Observatory website [3].
- **SSO (or SO)**: It is a Sun-synchronous orbit also called a heliosynchronous orbit is a nearly polar orbit around a planet, in which the satellite passes over any given point of the planet's surface at the same local mean solar time [4].
- ES-L1 :At the Lagrange points the gravitational forces of the two large bodies cancel out in such a way that a small object placed in orbit there is

- in equilibrium relative to the center of mass of the large bodies. L1 is one such point between the sun and the earth [5].
- **HEO** A highly elliptical orbit, is an elliptic orbit with high eccentricity, usually referring to one around Earth [6].
- ISS A modular space station (habitable artificial satellite) in low Earth orbit. It is a multinational collaborative project between five participating space agencies: NASA (United States), Roscosmos (Russia), JAXA (Japan), ESA (Europe), and CSA (Canada) [7]
- MEO Geocentric orbits ranging in altitude from 2,000 km (1,200 mi) to just below geosynchronous orbit at 35,786 kilometers (22,236 mi). Also known as an intermediate circular orbit. These are "most commonly at 20,200 kilometers (12,600 mi), or 20,650 kilometers (12,830 mi), with an orbital period of 12 hours [8]
- **HEO** Geocentric orbits above the altitude of geosynchronous orbit (35,786 km or 22,236 mi) [9]
- GEO It is a circular geosynchronous orbit 35,786 kilometres (22,236 miles) above Earth's equator and following the direction of Earth's rotation [10]
- PO It is one type of satellites in which a satellite passes above or nearly above both poles of the body being orbited (usually a planet such as the Earth [11]

some are shown in the following plot:

TASK 2: Calculate the number and occurrence of each orbit

Use the method .value_counts() to determine the number and occurrence of each orbit in the column Orbit

```
In [7]: # Apply value_counts on Orbit column
        df['Orbit'].value_counts()
Out[7]: Orbit
         GT0
                  27
         ISS
                  21
         VLE0
                  14
         P0
                   9
         LE0
                   7
                   5
         SS0
                   3
         ME0
                   1
         HE0
         ES-L1
                   1
         S0
                   1
                   1
         GE0
         Name: count, dtype: int64
```

TASK 3: Calculate the number and occurence of mission outcome of the orbits

Use the method .value_counts() on the column Outcome to determine the number of landing_outcomes .Then assign it to a variable landing_outcomes.

```
In [8]: # landing_outcomes = values on Outcome column
        landing_outcomes = df['Outcome'].value_counts()
        landing_outcomes
Out[8]:
        Outcome
        True ASDS
                        41
        None None
                        19
        True RTLS
                        14
        False ASDS
                         6
        True Ocean
                         5
                         2
        False Ocean
        None ASDS
                         2
        False RTLS
                         1
        Name: count, dtype: int64
```

True Ocean means the mission outcome was successfully landed to a specific region of the ocean while False Ocean means the mission outcome was unsuccessfully landed to a specific region of the ocean. True RTLS means the mission outcome was successfully landed to a ground pad False RTLS means the mission outcome was unsuccessfully landed to a ground pad. True ASDS means the mission outcome was successfully landed to a drone ship False ASDS means the mission outcome was unsuccessfully landed to a drone ship. None ASDS and None None these represent a failure to land.

```
In [9]: for i,outcome in enumerate(landing_outcomes.keys()):
    print(i,outcome)

0 True ASDS
1 None None
2 True RTLS
3 False ASDS
4 True Ocean
5 False Ocean
6 None ASDS
7 False RTLS
```

We create a set of outcomes where the second stage did not land successfully:

```
In [10]: bad_outcomes=set(landing_outcomes.keys()[[1,3,5,6,7]])
bad_outcomes
```

TASK 4: Create a landing outcome label from Outcome column

Using the Outcome, create a list where the element is zero if the corresponding row in Outcome is in the set bad_outcome; otherwise, it's one. Then assign it to the variable landing_class:

```
In [11]: # landing_class = 0 if bad_outcome
    # landing_class = 1 otherwise

landing_class = []

for outcome in df['Outcome']:
    if outcome in bad_outcomes:
        landing_class.append(0)
    else:
        landing_class.append(1)
```

This variable will represent the classification variable that represents the outcome of each launch. If the value is zero, the first stage did not land successfully; one means the first stage landed Successfully

```
In [12]: df['Class']=landing_class
          df[['Class']].head(8)
Out[12]:
             Class
                 0
          0
                 0
          2
                 0
          3
                 0
          4
                 0
          5
                 0
          6
                 1
          7
                 1
In [14]: df.head(5)
```

Out[14]:		FlightNumber	Date	BoosterVersion	PayloadMass	Orbit	LaunchSite	(
	0	1	2010- 06- 04	Falcon 9	6104.959412	LEO	CCAFS SLC 40	
	1	2	2012- 05- 22	Falcon 9	525.000000	LEO	CCAFS SLC 40	
	2	3	2013- 03- 01	Falcon 9	677.000000	ISS	CCAFS SLC 40	
	3	4	2013- 09- 29	Falcon 9	500.000000	РО	VAFB SLC 4E	
	4	5	2013- 12-03	Falcon 9	3170.000000	GTO	CCAFS SLC 40	

We can use the following line of code to determine the success rate:

```
In [15]: df["Class"].mean()
```

Out[15]: np.float64(0.66666666666666)

We can now export it to a CSV for the next section, but to make the answers consistent, in the next lab we will provide data in a pre-selected date range.

```
df.to_csv("dataset_part_2.csv", index=False)
```
